How CivicVerify AI works, nationally

One central country server holds every record — offline and append-only. State servers and embassy servers each hold a full mirror. Universities and agencies feed data in; anyone needing verification queries the nearest server for an instant, auditable answer.

Why this design catches fraud and speeds up governance

- ✓ **Offline at every tier** — no cloud dependency, works during network or power outages
- ✓ **Append-only ledger** — old records preserved when corrections happen; every change is auditable
- ✓ **Mirrored source of truth** — a UK embassy sees the same version history the country server has
- ✓ **CivicVerify AI runs at each node** — instant answer, no manual cross-checking
- ✓ **Fake certificates cannot slip through** — cert numbers not in the registry are flagged automatically
- ✓ **Peter's example** — name change adds a new version; embassy sees both, verifies confidently

Reading the diagram: Data flows down through three tiers. Producers at the top push records into the Country Server (amber hub). The Country Server never deletes — every correction is appended as a new version, giving a full audit trail. State Servers (Nigeria) and Embassy Servers (abroad) each hold a full offline mirror. Requesters query the nearest server and get an instant, auditable answer without touching the internet.
